library(pander)
```

A univariate normal, or Gaussian, linear model is defined as follows. Assume that our data consists of n independent pairs of observations:

$$\mathcal{D} = \{ (y_1, \vec{x}_1) \dots (y_i, \vec{x}_i) \dots (y_n, \vec{x}_n) \},\$$

where each $y_i \in \mathbb{R}$ and $\vec{x}_i \in \mathbb{R}^K$. We then model this data as follows:

$$y_i \sim N(\beta_0 + \sum_{k=1}^K \beta_k x_{ik}, \sigma^2), \text{ for } i \in \{1, 2 \dots n\}.$$

Demonstration

Here, we generate some data.

Here, we fit the model with maximum likelihood estimation:

```
M <- lm(y ~ x + z, data=Df)
pander(summary(M))</pre>
```

	Estimate	Std. Error	t value	$\Pr(> t)$
(Intercept)	1.438	0.2663	5.402	2.136e-06
\mathbf{x}	2.191	0.1624	13.49	8.881e-18
$\mathbf{z}\mathbf{y}\mathbf{e}\mathbf{s}$	-0.2406	0.3544	-0.679	0.5005

Table 2: Fitting linear model: $y \sim x + z$

Observations	Residual Std. Error	R^2	Adjusted R^2
50	1.231	0.8026	0.7942
